Developing countries

ABSTRACT

The level of job satisfaction has a significant impact on an individual's job behaviors. In any organization, job satisfaction affects performance as part of job behavior significantly. Its importance in developing nations like Bangladesh is clear. The present study investigated the relationship of Bangladesh industrial workers' job satisfaction level and job behavior as workplace behaviors that affect job performance. This quantitative study collected data from respondents using a standardized questionnaire. A sample of 300 Bangladeshi industrial workers was chosen. An 8-item self-report (JPI) measurement scale was utilized for the evaluation of job performance. The measurement of job satisfaction was conducted through the utilization of the job satisfaction index (JSI). Statistical Package for Social Science (SPSS) 24.0 version was used for data and regression analysis in this study for hypotheses testing. The analysis found a disproportionate amount of people satisfied with their jobs. The study revealed that job satisfaction is a critical job behavior that affects job performance. The study also indicated that job-related factors affected job performance more than personal traits. Also found, employees who reported high levels of job satisfaction also reported higher levels of job performance. Bangladeshi industrial regulators and mill authorities can use the results to design regulations that boost employee performance and work happiness. It can also be used to evaluate employee treatment and how job satisfaction affects other job behaviors to guide organizational decisions and initiatives.

1. Introduction

In industrial settings, the relationship between employee work satisfaction and job behavior has significant consequences for organizational success. This study delves into the subtle dynamics of this relationship, with the overriding goal of understanding the impact of employee work satisfaction on their job behavior as viewed through the lens of job performance. While current literature has thoroughly

explored the relationship between job satisfaction and job behavior, significant study vacuum remains in the specificity required to understand these dynamics within the unique setting of industrial environments. Workers in industrial settings face unique obstacles, ranging from physical demands to safety issues, needing a customized study that goes beyond the broad insights provided by existing research. Employees' levels of commitment to the company, stress at work, absenteeism, and turnover can all be affected by how satisfied they are with their jobs. It

may also affect productivity, employee engagement in problem-solving, and the amount of effort that workers put into improving their work. Yustina and Valerina (2018) found that when people are satisfied with their employment, it feels less like labour and more like play. Getting up and going to work each day is easier for people who enjoy what they do. Stress has detrimental effects on work performance, psychological wellness, and physical health; both are mitigated by feeling appreciated and appreciated at work. Furthermore, satisfied workforces are more productive and enthusiastic in their work (Katebi et al., 2022; Muhammad et al., 2022). On the other hand, satisfied workers are more likely to go above and beyond in their work. This upbeat outlook might rub off on one's teammates and boost productivity. Although studies have shown a correlation between job satisfaction and productivity, reducing stress levels can have a beneficial effect on performance (Alrazehi et al., 2021). There has been enough debate (UKessays) of the consequences of job happiness and discontent on employee behaviors, which in essence affect the corporation's operations and performance. According to a research by the (EU 2019) Statistics Centre, on average, just 24.6 % of employees in the 27 member states are completely happy with their jobs. Managers and businesses have been puzzling over the peculiar and elusive link between job performance and employee happiness for decades. Hsieh (2016) argues that job satisfaction is a key notion that might influence labor market behavior because it has such a significant effect on performance, accident rates at work, effort put in, turnover, absenteeism, and employee relations. According to research by Bjaalid et al. (2020), job satisfaction has a momentous effect on high performance as a behavior on the job. As a result, Jing (2018) argued that better performance leads to greater job satisfaction, higher rates of staff retention, and greater corporate loyalty, all of which boost productivity. Several studies (e.g. Badrianto and Ekhsan, 2020; Gazi et al., 2023) have demonstrated that job satisfaction has an effect on job performance as a cog of job behaviors (Gazi et al., 2022). Despite their apparent differences, job happiness and workplace behaviors are intrinsically linked. Modern managerial actions, and by extension, the goals of all businesses, are focused on maximising employee happiness in order to boost productivity on the job (Thang and Nghi, 2022). Organizational leaders are strongly encouraged to choose the top performers so that their companies can meet the difficulties posed by the 4.0 technologies and the industrial transformation of the twenty-first century (Kampf et al., 2021). However, components and materials that provide a better level of enjoyment are necessary in order to guarantee work performance. Many experts are of the opinion that if employees are happy in their jobs, they will do work that is worthy of being paid for. Not only is the highest degree of job satisfaction guaranteed, but it also helps to cultivate a lasting devotion among the workers

The theoretical foundation of our study, titled "Analyzing the Impact of Employee Job Satisfaction on Their Job Behavior in the Industrial Setting: An Analysis from the Perspective of Job Performance," is firmly grounded in fundamental theories of organizational behavior and industrial psychology. The Job Characteristics Model and Herzberg's Two-Factor Theory are utilized to comprehend the factors that lead to employee satisfaction and the outcomes that result from it (Tingo and Mseti, 2022; Bayona et al., 2020). Social exchange theory enhances the examination of the mutual connection between job happiness and job behavior, highlighting the potential good behaviors that can arise from receiving favorable treatment (Ghazmahadi et al., 2020). The study of expectancy theory examines how employees' beliefs about the relationship between job happiness and job performance impact their actions within an industrial setting (Nguyen and Duong, 2020; Bai et al., 2023). Furthermore, the study of performance appraisal can be enhanced by considering broader organizational behavior frameworks and theories, such as Goal Setting Theory. These frameworks provide a comprehensive context for analyzing the complex relationship between job satisfaction and job behavior, specifically in terms of job performance (Zhang et al., 2019). This study seeks to combine known ideas in order to create a strong framework that enhances our comprehension of

the intricate dynamics inside the industrial organizational setting. Modernizing Bangladesh's industrial sector has required many action initiatives. In addition to technology and infrastructure, job satisfaction may assist industry's workers perform better (Inayat and Khan, 2021; Tan et al., 2023). Supervisory policymakers can customize work satisfaction-based reward systems to promote industry efficiency. The industry will profit from more devoted, motivated, and pleased workers. Numerous researches have examined the link between job satisfaction and job behavior, most notably performance (Omar et al., 2020; Badrianto and Ekhsan, 2020; Mariam and Ramli, 2020; Zhang et al., 2019). Unfortunately, Bangladeshi industrial sector workers' job satisfaction and performance have been seldom studied. None of the Bangladeshi researcher has examined how worker satisfaction affects job behavior. Even global surveys show no sufficient study on job satisfaction and job behavior in regards performance in Bangladesh. That's why current research is commendable.

This study recognizes the need for a more concentrated assessment and develops research questions to bridge this gap, with the goal of uncovering the nuanced aspects of job satisfaction that have a major impact on observable job behaviors in the industrial sector. By distilling the identified research need into concrete inquiries, this study aims to provide not only theoretical insights but also practical consequences for corporate executives and policymakers. Through this investigation, the study hopes to provide a complete analysis that adds to the existing literature and provides strategies for improving overall performance in industrial organizations. In order to close this gap, the study question is designed to investigate how job satisfaction among employees affects their behavior on the job in an industrial context. The goal of identifying the precise processes via which job pleasure affects job behavior within industrial organizations guides the translation of the research gap into the research topic. The study aims to gain insights that can guide focused actions and strategies to improve overall organizational performance by focusing just on this specific situation. Questions for Research are as RQ1: How does employee job satisfaction influence job behavior in the industrial setting? and RQ2: What are the underlying mechanisms and contextual factors that contribute to this relationship?

Although prior research has established the link between employee job satisfaction and job behavior, there are still shortcomings in understanding the details of this relationship in developing countries, especially in the Bangladeshi industrial setting. Past research tends to lump data together from very different sectors without accounting for different drivers of satisfaction and behavior in different contexts. The literature on developed economies is, for the most part, dominant and leaves us with a huge lack of understanding regarding how culture and economy influence employee experience in Bangladesh. Also, the interaction between critical work-related factors pay, opportunities for promotion, job security, and working conditions, and their combined effects on job satisfaction and performance remain understudied. Moreover, well-established theoretical models such as the Job Characteristics Model and Herzberg's Two-Factor Theory are still to be tested in the Bangladeshi industrial environment. This research seeks to address these lacunae by empirically probing the relationship between job satisfaction and job behavior, and performance in particular, in the context of the complexities of the Bangladeshi industries. By comparing job-related and personal variables, this work aims to contribute to knowledge of how these variables interact and inform employee behavior in emerging industrial workplaces.

While this study provides a meaningful understanding of the link between employee job satisfaction and job behavior in the context of the Bangladeshi industrial setting, it also highlights many gaps in the research that need further investigation. Firstly, the concentration on five state-owned enterprises restricts the applicability of the results; more studies are needed covering a broader diversity of sectors, including private and service sectors, in order to better understand the relationships between job satisfaction and performance in a wider variety of settings. Moreover, this is a cross-sectional study, meaning that it

tells us only what job satisfaction and performance are like at a single point in time. Longitudinal studies could track over time changes in job satisfaction and see how they lead to changes in job behavior and performance under changing economic or organizational circumstances. Furthermore, while this study is situated in Bangladesh, additional research could examine how cultural factors influence the relationship between job satisfaction and job behavior across different nations or cultural settings, particularly in other developing economies.

The body of our paper is separated into distinct parts. The initial sections provide an introduction to our study, its background, and its ultimate purpose. To examine previous research in our subject and identify any gaps in the literature, we conduct a literature review in section two (2.0). The second lesson provides a literature review to help guide the development of a framework for study and hypotheses. In the third section, we describe the research strategy and data sources we used. The analytical and empirical outcomes of this research are presented and illustrated statistically in [Section 4](#). The results of the investigation are discussed (section-5.0), with reference to relevant earlier research. In the final two parts of this series, we not only examine the study's theoretical as well as practical consequences but also present the findings themselves. The final section includes a conclusion and list of references and annotated bibliographies of the sources used to compile the data and draw the findings presented here.

2. Literature review and hypotheses development

2.1. Job behavior

How someone acts on the job is indicative of how much they appreciate their job. The management or job operator's actions can be inferred from data on absenteeism, accidents, turnover, and the quality and quantity of output ([Rahman and Gazi, 2022](#)). One of the primary aims of organizational behavior science is to explain why people act in certain ways ([Bayona et al., 2020](#)). We will focus on four key areas: productivity in the workplace, employee contentment, absenteeism, accidents, and turnover. [Vroom \(1964\)](#) does an excellent job of exploring the connection between job satisfaction and different aspects of occupational behavior. Vroom organizes studies according to the factors that contribute to contentment in the workplace. He classifies them as investigations into issues such as employee departures, absences, mishaps, and productivity ([Huang, 2019](#)). The unique aspects of job satisfaction and job enthusiasm in emerging economies are crucial to consider when evaluating these concepts in general, write [Jelena et al. \(2018\)](#).

Numerous studies on the topic of occupational contentment and targeted behavior have shown generally positive findings. Attitudes toward work have been linked to a wide variety of specific tasks in the workplace ([Gazi et al., 2023](#)). Stronger and more conceptually significant correlations exist between global job satisfaction and behavioral and physiological families than between global work satisfaction and one's behaviors ([Gazi et al., 2023](#)). However, the takeaway is that a wide variety of crucial individual behaviors are routinely linked to contentment in one's profession ([Khaleque & Choudhury, 1984](#)). However, if an attenuation the choice of sample variance, and challenges due to estimation of different behaviors are considered in studies examining the connections between stated job satisfaction and job behavior on the actual job performance, the guesstimates of population correlations are significant and may offer a more complete framework for understanding the attitude/behavior nexus ([Çelik & Oral, 2021](#)).

2.2. Personal traits, Job-related aspects, and Job satisfaction

Employment satisfaction can be quantified as the extent to which one derives positive emotional emotions from their employment. As a result, studies of employee happiness on the job are commonplace ([Diana et al., 2020](#)). Satisfaction with one's job is defined as an affective variable

resulting from analysis of one's working conditions ([Jongo et al., 2019](#); [Mitsakis and Galanakis, 2022](#)). One of the many variables that lead to appreciating one's work and feeling good about oneself is job satisfaction. When someone says, "I am satisfied with my job," they should mean it on several levels, including the emotional, intellectual, and physical ([Gazi et al., 2021](#); [Muhammad et al., 2023](#); [Badrianto and Ekhsan, 2020](#)). The allure of one's job is a strong motivator for happiness at work. [Mesurado et al. \(2021\)](#) argued that an employee's level of happiness on the job is proportional to the amount of effort they put into their work. The positive emotional state achieved via successful completion of assigned tasks has been shown to promote job satisfaction ([Al-Haidan et al., 2022](#); [Oluwatayo and Adetoro, 2020](#); [Nduati and Wanyoike, 2022](#); [Siahaan, 2022](#); [Hudson et al., 2020](#)).

Numerous research ([Zeng et al., 2021](#); [Lee et al., 2020](#)) shows that there are robust associations between job satisfaction, job-related aspects and personal factors. The study highlights the factors that influence job satisfaction, including personal traits and job-related aspects. According to [Wang et al. \(2024\)](#), older employees tend to have higher job satisfaction due to their accumulated experience and sense of security, although age-related declines in cognitive abilities may negatively impact satisfaction ([Lee et al., 2024](#)). Education, experience, and marital status are also positively correlated with job satisfaction ([Cheng et al., 2024](#); [Li et al., 2024](#); [Zhang et al., 2024](#)). Job-related aspects, such as pay ([Cheng et al., 2024](#)), promotion ([Liu et al., 2024](#)), job security ([Wang et al., 2024](#)), autonomy ([Li et al., 2024](#)), and working conditions ([Zhang et al., 2024](#)), also play a crucial role in determining job satisfaction. Research suggests that overall job satisfaction is positively correlated with these factors ([Cheng et al., 2024](#); [Stepanova et al., 2024](#)), and organizational commitment is also positively correlated with job satisfaction ([Liu et al., 2024](#)). However, high levels of job burnout are negatively correlated with job satisfaction, indicating that employees who experience burnout are more likely to be dissatisfied with their jobs ([Wang et al., 2024](#); [Gazi et al., 2023](#)).

Several studies, including [Santhoshkumar et al. \(2019\)](#) and), have looked at personal factors as predictors of job satisfaction. However, [Li et al. \(2024\)](#) revealed that there is no significant correlation between personal factors and job satisfaction, excluding sex. Employees of different ages report different levels of job satisfaction ([Gazi et al., 2023](#)). According to research conducted by [Anastasiou and Garametsi \(2021\)](#), marital status and other personal characteristics, such as sex and socioeconomic standing, did not significantly affect job satisfaction. However, education did. Several credible research ([Lee et al., 2020](#); [Muskat and Reitsamer, 2020](#); [An et al., 2020](#)) have demonstrated the effect of job-related aspects on job satisfaction. [Islam et al. \(2020\)](#) found that factors such as an individual's personality, culture, and demographics have a negligible effect on job satisfaction. [Lange \(2021\)](#) found that people's age, gender, and race all played a role in how satisfied they were with their jobs. According to [Santhoshkumar et al. \(2019\)](#), factors such as having children, getting married, and reaching academic goals can all affect how fulfilled one feels at work. [Nguyen et al. \(2020\)](#) found that neither age nor gender nor education level significantly correlate with satisfaction. Workers of all ages express happiness with their jobs, a finding that is not statistically significant according to [Islam et al. \(2020\)](#). [Mesurado et al. \(2021\)](#) stated that a favorable and strong relationship exists between demographic characteristics and job satisfaction. Job satisfaction was positively correlated with age and experience, and there were no significant gender disparities in this regard, according to research conducted by [Lee et al. \(2020\)](#). According to [Lange \(2021\)](#), dedication and contentment in the workplace are influenced by positive cultural elements. According to [Gazi et al. \(2023\)](#) study, there is no statistically significant relationship between age, years of experience, or gender and job satisfaction. [Kumar \(2021\)](#) found that age, job level, skills, and experience were marginally associated to university faculty job satisfaction. [An et al. \(2020\)](#) found that job position and age affected job satisfaction, but education, race, genders, parental status, and employment tenure did not. By [Islam et al. \(2020\)](#), demographic

parameters like age, marital status, present employment status, and wage seem to greatly affect job satisfaction. Gazi et al. (2022) found strong correlations between industrial workers' job satisfaction and experience, gender, or age.

Numerous studies demonstrated a continuous connotation between job-related characteristics and job satisfaction. An et al. (2020) examined Ghanaian construction industrial job satisfaction indicators. The results showed that recognition, the task, working atmosphere, leadership, and job security were more important than wages in determining job satisfaction in the construction industry. Kumar (2021) found that work atmosphere, overall compensation, career progress, and job status influence satisfaction with work and are connected. Muskat and Reitsamer (2020) found a relationship between working conditions and job satisfaction. Work happiness is strongly influenced by pay (An and Mikhaylov, 2020). Income is the biggest factor in job satisfaction, according to research (Gazi et al., 2022). Recognition, legwork, and relationships drive workplace happiness, according to Tran and Tran (2020). Some job factors were favorably connected with overall job satisfaction, according to Yusuf (2019). Joshi (2019) found a correlation between promotion, supervisor demeanor, phrasing, working environment, fair job trajectory, other financial rewards, and coworker pro-social behavior. According to Kartika et al. (2019), job security (.289) and adequate pay (.279*) highly connect with tourism industrial workers' job satisfaction. Tran and Tran (2020) examined hotel staff satisfaction. This study shows that structural characteristics positively affect work satisfaction. However, environmental factors negatively impact job happiness. According to Fikire (2021), income and incentives, work environment, and culture are the main factors affecting industrial worker satisfaction.

A study by Gazi et al. (2023) found that overall job satisfaction is positively correlated with various aspects of the job, including pay, promotion, job security, autonomy, and working conditions (Karaferis et al., 2022; Mutalimov et al., 2021). Yuan et al. (2022) also claimed that worker circumstances, demographics, and career or job type expectations affect job satisfaction. Additionally, job satisfaction is the employee's emotional response to the employment environment (Fikire, 2021). Job satisfaction is complex and influenced by personal and contextual factors, according to (Ni et al., 2020). It must address personal and social elements that affect job satisfaction (Cheng et al., 2021). The literature splits job satisfaction into personal and job-related components in this section. After considering the above, here are some hypotheses we've come up with.

Hypotheses 1. : The respondents' total job satisfaction is not significantly influenced by personal traits.

Hypotheses 2. : The influence of job-related parameters on the total job satisfaction of the respondents is not statistically significant.

2.3. Job performance

According to data compiled by Bangladeshi Industries (Omar et al., 2020), worker productivity is a major factor in determining a company's success. An individual's level of knowledge and skill are more important than their position or employer when it comes to accomplishing accuracy job task (Rachman et al., 2020). According to Mariam and Ramli (2020), job-relevant behaviors are favorable in achieving job performance, which is essentially the quality of the work done. According to Karaferis et al (2022), success is "what the organization hires one to do and accomplish effectively." With the help of hardworking employees, visionary leaders can construct remarkable businesses. The individual's performance on job-related tasks is also a factor (Torlak and Kuzey, 2019). In most cases, high-performing employees will help leaders construct effective companies (Kim and Cho, 2020). Job performance, as defined by Eliyana and Sridadi (2020), involves fulfilling duties that facilitate the production of a product or service and those that carry out administrative tasks. According to Maryani and Adnan (2022),

employee job performance is a concept that broadly refers to whether or not a person accomplishes their task appropriately. Job performance, according to Wijaya and Suwandana (2022), is an indicator of how successfully employees meet job criteria. Johnson and Lake (2019) defined job performance as the outcome of an individual's innate talent, acquired skills, and applied effort in a given setting. Nuangjamnong (2022) defines performance as the quality and quantity of work completed by individuals in regards to the responsibilities and work errands consigned by the organization (Peiró et al., 2020). Thant and Chang (2021) defines employee job performance as from the viewpoint of the variables or procedures pertaining to human resources that directly affect such a relationship. As a result, companies must implement strategies to ensure consistent performance from employees (Peiró et al., 2020). If an organization wants its employees to provide their very best, it must accommodate their particular needs and preferences.

2.4. Job satisfaction and job behavior in regards job performance

Salary, advancement, job security, employment status, conditions at work, benefits, trainings, and personal variables all had a role in determining the independent variable of job satisfaction. Job behavior as it relates to performance on the job is the focus of this research (Ramli, 2020). When workers are happy, they tend to work harder. The quantity, performance, promptness, attendance on the job, cohesiveness at work, efficiency of the task done, and the efficacy of the work completed all contribute to an employee's performance (Rodrigo et al., 2022). Leadership style was also strongly related to job performance, and job happiness was favorably related to job-related behavior and performance (Goetz and Wald, 2022). Multiple researchers have examined the correlation between job satisfaction and productivity (Arijanto, 2022; Saragih et al., 2020; Rodrigo et al., 2022; Kumar, 2022). An association between job happiness and expected performance was found by Sánchez-Sánchez and Puente (2021).

Vrooms (1964) suggested that workers who are happy in their jobs may be more productive overall. Bonaventure et al. (2021) found that there is a positive association between job satisfaction and performance, and that regression analysis confirmed the significance of the rapport between job satisfaction and performance. Agustina et al. (2022) argued that job satisfaction is foundational to productivity in the workplace. Widyaningrum and Rachman (2019) found that there is a robust relationship between employee motivation and performance. Bayona et al. (2020) reported that among Jordanian workers, job satisfaction is more important than salary or compensation levels in determining productivity. Yuan et al. (2022) found that happy employees tend to be more productive. Omar et al. (2020) also performed research into the link between marketing staff happiness and the success of adaptive selling strategies. A strong connection was found between sales performance and employee happiness in this study. Data analysis using correlation and regression, as noted by Peiró et al. (2020), provided strong evidence of a favorable relationship between job satisfaction and performance. Goetz and Wald (2022) analyzed the correlation between employee loyalty and productivity among 43 government employees in Indonesia. They found that dissatisfaction with one's employment negatively impacts productivity. Rachman (2021) shows that workers are willing to sacrifice a great deal of job pleasure in exchange for exceptional productivity. Job satisfaction and a pleasant work environment are two factors that might boost productivity in the workplace. Hassan et al. (2020) found that being happy at work significantly boosts productivity. Pay, career growth prospects, teamwork, and the nature of the task themselves were also found to have a marginally positive link.

The workforce's impact on artificial intelligence (AI) technologies has been the subject of a nuanced examination within the dynamic industrial environment. The intricate interplay between labor productivity growth and AI-driven partial job displacement necessitates careful consideration, particularly with regard to the effects on employee job

satisfaction and behavior (Lazaroiu and Rogalska, 2023). The extant body of literature underscores the complex and diverse characteristics of job displacement, recognising that it can give rise to both advantageous prospects and formidable obstacles (Rohmawati et al. 2020). Academics emphasize the criticality of attending to employee apprehensions and modifying organizational frameworks in order to cultivate job satisfaction in the face of technological advancements (Nemțeanu et al., 2022). Employee behavior is impacted by the industrial sector's AI-induced transformation; performance may be negatively impacted by perceived threats to job security (Nemțeanu et al., 2022). Furthermore, effective training programs and supportive work environments are prerequisites for the correlation between AI integration and labor productivity growth (Lazaroiu and Rogalska, 2023). The present literature review highlights the interrelatedness of various concepts.

As shown by Gün et al. (2021), there is a definitive link between job performance and job happiness. Research by Gazi et al. (2023) showed that job satisfaction is high across all industries. Employees' job happiness has been found to be closely related to leadership, productivity, compensation, and motivation. Affective commitment from workers was found to increase productivity. This will encourage them to put forth greater effort in their task. Satisfying employees who are devoted to the organization leads to improved job performance (Khan et al., 2022). Maryani and Adnan (2022); Yandi and Bimaruci Hazrati Havidz (2022) found that employees who report feeling positive about their jobs are more likely to be engaged in their work, complete their assignments on time, create quality results that are free of mistakes or oversights, and demonstrate a willingness to take on additional responsibilities while maintaining their present level of productivity. So, we'd like to put up the following hypothesis:

Hypothesis 3. : Job satisfaction affects Bangladesh's industrial workers' performance.

While previous literature extensively investigates the relationship between job satisfaction and job performance, our study adds innovation by delving deeper into the intricacies of this relationship within the particular framework of the industrial setting. We seek to provide a deep understanding of the aspects that lead to employee job satisfaction and, as a result, impact their workplace behavior. This study stands out because it emphasizes the industrial setting, recognizing the unique problems and opportunities it brings to both employees and enterprises. (Fig. 1)

3. Research methodology

This study investigates the relationship between employee job satisfaction and job behavior, with a particular emphasis on job performance, in the context of the global industrial landscape. As firms operate on a global basis, knowing the subtle interaction between these factors (personal and job factors) becomes critical for long-term competitiveness. The research technique is intended to contribute to the broader international literature by taking into account cross-cultural influences on job satisfaction and behavior. Our approach is informed by a comprehensive analysis of existing research, which takes into account the diverse cultural and organizational settings that impact these dynamics. A qualitative descriptive technique was used for the purpose of conducting an investigation on the overall performance of industrial workforces in Bangladesh, specifically the level of job satisfaction experienced by workers in different stated owned industry, we hope to provide a comprehensive knowledge that is applicable not only to the specific industrial context under consideration but also to varied worldwide environments. By combining the findings of this study, we want to add significantly to the continuing international debate about the important link between employee job satisfaction, job behavior, and organizational performance in the industrial sector.

3.1. Data collection procedures and sampling

In light of the objectives of the study as well as the findings of the literature review, the methodology is essentially interpretative and systematic in its approach. The questionnaire was based on a previously validated instrument, which was adapted to fit our specific research objectives. The original questionnaire was developed by Brayfield and Rothe (1951) and Fisher and Locke (1992) and has been used in various studies in the field (Yuan et al., 2022, 2023; Li et al., 2024; Nasution and Widodo, 2024). Present study used this adapted questionnaire to collect data from participants, and has provided more details on the specific questions and subscales used in the section of Measuring Scales and Instruments. In our study, we used proportionate stratified random sampling to select participants from our population of interest. We ensured that each participant received their own questionnaire and kept a close eye on the amount of time they had to respond so that we could avoid conducting the same poll more than once. Following the elimination of the 197 total questionnaires that did not contain the barest least of employee information, a total of 303 were found to be valid. For the purposes of efficient data collecting and analysis, this number was

Fig. 1. Research Framework.

rounded up to 300 respondents. The study's universe included 57535 workers (permanent workers 28093, seasonal workers 23155, and no work no pay workers 6287) employed in South Zone of Bangladesh's industrial sector (BSFIC 2021). All of them work in production unit. The study's population consisted of 6212 employees from the five selected unit of five different industries. Workers from these industrial units were chosen using proportionate stratified sampling. The study's overall sample size was 300 respondents, which represents 4.83 percent of the study's population. Utilizing the Yamane (1967) formula, the sample size was calculated.

BSFIC, BJMC, MTJ, BCIC which are the regulatory body of Bangladesh's industrial sector and a public sector institution, is responsible for compiling lists of all industry in the country. The researchers decided to look into five important industries located in various regions across Bangladesh for the aim of their study. In particular, the respondents' lists of five public-sector industry have been selected for the purpose of data collection. The complete selected sample is broken down into its component parts, employee level, and organization type, as shown in Table 1

The result was a valid response rate of 75.6 % across all questions. One hundred supervisors (33.33 %) and two hundred employees (66.67 %) took part. 33.67 % of all responders fell into the 55+ age bracket. However, the next largest demographic was those between the ages of 45 and 55, accounting for 26.33 percent of all respondents. All of the foremen (100 %) were middle-aged guys. And 8.33 % of those surveyed had no education beyond the eighth grade. Furthermore, just 5 percent of workers and 15 percent of foremen were reported to be literate, with workers having a higher average level of schooling (3.29 vs. 2.68). The highest share of responders (36.67 %) came from the 30- to 40-year-old bracket. Nonetheless, 20.33 percent of those polled is higher than any other group. Foremen made up 89 % of the group with 40+ years of experience, while laborers made up 47 % of the group with 0–15 years of experience. There were just 9 % of individuals who were not married.

3.2. Research design

This study utilized a thorough questionnaire as a research tool to evaluate the concepts of job satisfaction and job performance among employees in an industrial environment. The questionnaire was designed by including proven dimensions within each construct (Gazi et al., 2023; Yuan et al., 2023; Khaleque and Choudhury, 1984). Job satisfaction was assessed by considering various factors pertaining to the job and personal aspects, such as autonomy in decision-making, job status, job security, working conditions, boss's behavior, open communication, work autonomy, recognition of good work, and promotion. Particular attention was given to the crucial aspect of pay (Khaleque and Choudhury, 1984). Job performance was evaluated based on both quantitative and qualitative criteria, which encompassed factors such as the volume and caliber of work, job expertise, proactivity, innovation, teamwork, reliability, and personal growth (Sypniewska et al., 2023). The dimensions included in this study were derived from

well-established frameworks and literature on job satisfaction and performance measurement (Yen et al., 2023). The purpose of the structured questionnaire was to gather detailed information about the factors that affect employee happiness and how these factors influence job behavior in an industrial setting (Herzberg et al., 1957; Vroom, 1964).

A questionnaire was also devised in order to investigate the levels of job satisfaction associated with 11 distinct aspects of the profession. The purpose of the Khaleque and Choudhury (1984) questionnaire was to assess respondents' levels of contentment with 11 distinct employment-related factors (MSF). Many researchers argue that these to be covered a diversity of yet expressive portions that were constituted of the questionnaires, which obligate have an effect on employee behavior (Yang et al., 2019; Herzberg et al., 1957; Vroom, 1964; Locke, 1976). These sections were covered in (Yang et al., 2019; Herzberg et al., 1957; Vroom, 1964; Locke, 1976). Respondents were asked to indicate their level of pleasure or unhappiness with each of these specific characteristics by selecting either a "Yes" or "No" response from a drop-down menu. A questionnaire was used to determine the degree to which workers were satisfied with the various aspects of their jobs by collecting their responses. The item structure was established based on past research that covered pay, job security, promotion, status at work, superior behavior, work autonomy, open communication, and working conditions (Gazi et al., 2022; Yuan et al., 2022) carried out these studies. An item that corresponds to each job attribute investigates the significance of that attribute for the worker. It was requested of the respondents that they rank the importance of 11 variables related to work satisfaction (see Appendix-B). The value of this scale's Cronbach's Alpha was 0.91, which demonstrated both the fitness and logical validity of the scale as well as the reliability of the data set.

3.3. Measuring scales and instruments

3.3.1. Measuring job satisfaction

The eighteen components of Brayfield and Rothe (1951) Job Satisfaction Index (IJS) have been embodied such that they may be used to assess job satisfaction, which is the independent variable of this study (see Appendix-A). A group of students studying personnel psychology in the United States Army's specialized training program came up with a prototype scale as an assignment for class (Miller, 1991). This was done as part of their preparation for the program (Gazi et al., 2022; Smith et al., 1969). The Brayfield-Rothe's Job Satisfaction measurement scale (IJS) is a methodical scale that was designed thru the express intention of assessing workers' job-related characteristics (Oktaviani and Sopiah, 2022). Because it was preferable to provide an extensive obvious evidence of job satisfaction, the measurement scale contained numerous variables that made regard to specific areas of the work. This was done as it was a tendency to favor to provide such a sign. We used Likert scales, which include a five-point range and five different groups, angling from strongly agree to strongly disagree, with an impersonal response in the central. Responses are rated on a scale from one (extremely satisfied) to five (strongly disagree) with the highest possible score being one. From the empirical research conducted by Yuan et al. (2022), a total of

Table 1
Sample distribution table.

Name of the industry	Regulatory Authority	Level		Frequency	Percentage
		Foremen	Workers		
01	Sugar Industry	BSFIC	25	35	60
02	Jute Industry	BJMC	25	35	60
03	Textile Industry	MTJ	25	35	60
04	Cement Industry	BCIC	25	35	60
05	Fertilizer industry	BCIC	25	35	60
Total		125	175	300	100 %

Note: BSFIC = Bangladesh Sugar and Food Industries Corporation, BJMC=Bangladesh Jute Mills Corporation, MTJ=Bangladesh Ministry of Textile and Jute, BCIC=Bangladesh Chemical Industries Corporation

20 items were established for the purpose of assessing job satisfaction. These items were based on the scale that was developed by Brayfield and Rothe (1951), who developed 18 particular items.

The eighteen (18) item Bengali form of the job satisfaction scale was employed (Khaleque and Choudhury, 1984) to evaluate the level of contentment experienced by the workers in their jobs. There are nine (nine) components that are positive on this eighteen-item scale, and there are nine (9) parts that are negative. One point equals "strongly disagree," two points equals "disagree," three points equals "undecided," four points equals "agree," and five points equals "strongly agree." When it came to the items with a negative impact, the scoring was done backwards. A person's overall rating on the scale was determined by adding up all of the scores they received on the scale's individual components. The score of 45 is considered to be the "neutral point (Lazaroiu and Rogalska, 2023)," while the score of ninety (90) is the greatest possible score and the score of eighteen (18) is the lowest possible score (Nemţeanu et al., 2022). A higher grade suggests a better level of happiness with one's job. A higher grade suggests a better level of happiness with one's job. The level of dependability that this scale possesses is exceptionally high. Both the reliability and validity of the Brayfield and Rothe (1951) measure received scores of 0.89 out of a possible 0.93. Such multi-item job satisfaction measures have been extensively utilized in the fields of management and social science study, and both their reliability and validity have been shown (Lange, 2021; Nagy, 2002). In addition, these types of job satisfaction measures have been shown to have a high correlation with overall job satisfaction.

3.3.2. Measuring job performance

In their study, Valianawaty and Sutanto (2015) devised an assessment tool for self-evaluation of performance, with a total of eight components. The job performance measurement scale employed in this study was utilized by Yuan et al (2022), Wang and Chen (2020). The assessment scale utilized in this study required participants to retrospectively evaluate their performance on eight distinct tasks during their most recent work week. The participants were required to assess their performance in many areas, including QW-quality of work, QuW-quantity of work JK-job knowledge, IN-initiative, CR-creativity, CO-cooperativeness, UD-undependability, and PD-personal development, with a sense of confidence. The survey provided respondents with a selection of five response categories, spanning from 1 (indicating an exceedingly bad performance) to 5 (indicating a very high level of performance).

Further, the participant's immediate supervisor was tasked with providing feedback on how well each respondent performed on the job by assigning a score out of one hundred to each participant's overall performance. In this particular instance, a subjective conclusion was arrived at for there were no prejudiced standards that were utilized to evaluate the work of the industrial leaders. After the participants had finished filling out the questionnaire, the immediate supervisor noted the results of their performance on a separate sheet. The reliable units that every worker actually yields are referred to as "performance of the employee," and these authentic units are stated in terms of a hundred according to the standards that have been adopted by the organization of the relevant industrial employees.

When building a customized evaluation form to assess employee performance, we followed the process indicated in the psychometric literature for the distinct scale design procedure. The final draft featured a total of eight different aspects, which were as follows: work quality and quantity; job knowledge; initiative; creativity; cooperativeness; unreliability; and personal development. The evaluation of performance-related concerns was done using a Likert scale with five points. In addition to this, data sheets on job facets were included in this process. For the purpose of measuring employee performance, Valianawaty and Sutanto (2015) developed the JPI-Job Performance Indicator, which was subsequently adapted by Thang and Nghi (2022) and Badrianto and Ekhsan (2020). The JPI-Job Performance Indicator consists of eight

items that are each subjected to self-rating. When filled out this scale, participants were asked to score their performance on a total of eight activities and think back on the most recent work week that they had completed (see Appendix- C). In accordance to the previously established standards for the job performance scale, the composite reliability and Cronbach's Alpha values were found.

3.4. Reliability and validity test

Hair et al. (2017) stated that the Cronbach's Alpha value should be greater than 0.6, and the reliability of the composite must be greater than 0.7. Table 2 shows that the Cronbach's Alpha coefficient index for all variables are exists in between 0.67 and 0.71, and the composite reliability values for all variables in between 0.74 and 0.81.

It shows that all study model variables are reliable. KMO coefficients are greater than 0.50, and Bartlett's test sig. is 2.981 with a 0.000 margin of error. Inayat and Khan (2021) observed good construct validity and reliability. Because of this, all variables are reliable and can be used for further research.

3.5. Data analysis tools

Primary data was collected through questionnaires filled out by workers in the industrial sector of Bangladesh, specifically in the sated owned industry's production sites. The purpose of this research is to examine the relationship between job happiness and productivity. In this study, regression analysis was used to confirm the study's hypotheses and the reliability of the study results using data analyzed with SPSS, version 24.0. To begin, the companies' upper-level management had to agree to let the researcher into the building for the purposes of conducting interviews and gathering data.

4. Results

Because an employee's age, level of education, length of work experience, and marriage status can all have an effect on their overall job satisfaction, the respondents were divided into high and low groups so that the impact of these factors on the respondents' overall job satisfaction could be examined. Based on median age, experience, and education, the responses were split into two groups. In addition, the respondents were divided into married and unmarried subsets. In addition, the respondents were divided into married and single groups. Table 3 displays the average variations in work satisfaction between the various respondent demographics.

Table 3 illustrations that only the z-ratio for age groups is statistically significant. This finding implies that there is a considerable gap between the happiest workers in the youngest and oldest age brackets. Older respondents report greater happiness in their jobs than their younger counterparts. Overall job happiness can't be explained by factors like marital status, level of education, or years in the workforce.

According to Table 4, the unhappy participants' customized mean satisfaction was significantly and noticeably higher than that of the satisfied participants' for all job parameters except for boss's behavior, job position, and coworker relationships. Overall job satisfaction was shown to be significantly different from satisfaction with individual aspects of employment.

Table 4 displays the descriptive statistics for the job satisfaction-related parts of the performance evaluation procedure. The assessment of the completeness of the covariance matrices in the table also revealed that the pairwise correlation matrices of the dependent variables did not have the same degree of equality between the groups. Satisfied respondents had a mean pay score of 67.82 (S.D=6.97), while unsatisfied respondents had a mean pay score of 69.65 (S.D=9.58). Similarly, disgruntled workers averaged 70.89 out of 100 when asked to take part in decision making. Hair et al. (2017) stated that the Cronbach's Alpha value should be greater than 0.6, and the reliability of the composite

must be greater than 0.7.

Table 5 shows that workers who are relatively young report lower job satisfaction and performance. However, older workers tend to be more productive and content with their jobs. Workers in the industrial sector between the ages of 15 and 35 are the most unsatisfied (26.77 %) and the least productive (19.25 %), while those 55 and older are the least dissatisfied (10.28 %) and the most productive (28.02 %). The most contented workers were those between the ages of 15 and 35 (mean score: 69.17). Job satisfaction was also typically between 66.88 and 66.58 for those aged 35–55 and 55 and above. However, there was little variation in overall job satisfaction between generations. The respondents with a Literacy-Class V education level had the highest average work satisfaction (69.04) (Table 4).

According to the data in the table, workers with lower levels of

education report higher levels of satisfaction (28.11 %) than those with higher levels (8.14 %). Workers with bachelor's degrees or more also have a poor rate of productivity (30.71 %). Less educated workers perform better than their more educated counterparts. Table 5 also shows that the highest average job satisfaction was reported by those with 21+ years of experience. The data demonstrates that there is no statistically significant difference between the notches of job satisfaction reported by workers with varying levels of experience. Once again, one's satisfaction and output improve with age and maturity. Work output from personnel with over ten years of experience is generally positive. Workers with less experience are less happy at work (6.68 %) and less productive (4.07 %) than those with more experience.

Happier and more productive at work (51.02 %) are married workers. Once again, workers report lower levels of satisfaction with

Table 5
Descriptive statistics on job performance and job satisfaction based on personal traits.

Personal factors		Job performance		Job satisfaction		Mean	SD
		High	Low	High	Low		
Age	15–35 Years	11.25 %	19.25 %	11.23 %	26.77 %	68.87	69.17
	35–55 Years	14.25 %	18.23 %	12.50 %	13.20 %	66.88	6.88
	55 Years & above	27.12 %	10.03 %	25.45 %	11.08 %	67.92	68.72

	Class six–Class eight	15.12 %	11.17 %	18.47 %	23.82 %	68.25	8.25
	Graduate	16.08 %	30.71 %	8.14 %	15.64 %	60.82	68.91
Experience	1–10 Years	4.07 %	22.65 %	6.68 %	27.31 %	67.36	68.55
	11–20 Years	22.12 %	13.18 %	16.02 %	13.74 %	59.03	9.25
	21 Years & above	28.58 %	7.98 %	24.68 %	11.09 %	68.98	68.12
Level of Workers	Workers	28.12 %	19.4 %	28.12 %	19.31 %	67.86	8.98
	Foremen	38.64 %	13.87 %	39.87 %	12.88 %	68.54	8.78
Gender	Male	27.35 %	14.58 %	45.78 %	8.78 %	21.87	5.72
	Female	48.73 %	10.21 %	32.58 %	17.02 %	17.85	4.22
Marital Status	Married	51.02 %	7.68 %	39.35 %	15.12 %	68.21	9.08
	Unmarried	18.98 %	21.88 %	19.02 %	28.01 %	69.12	8.12

their jobs than foremen do. However, the foremen’s performance levels are encouraging (39.87 %). Table 5 further reveals that the median level of foremen and workers are 68.54 and 67.86 respectively. The difference between foremen’s and workers’ levels of job satisfaction was moderate but not statistically significant. In conclusion, men are more pleased with their jobs (45.78 %) than women (32.58 %), although women actually do a better job performance overall (48.73 %)

Cell sizes are not uniform, as shown by the descriptive data in Table 6. Because work satisfaction was a continuous measure, it was possible to utilize Leven’s test to determine whether or not the cells differed in their parity of error. Significant results (quality work, performance) in the test are below the significance level of 0.05, which contradicts the assumption of equal variances.

Table 7 shows the average dissimilarity from the Performance Evaluation Form sorted by reported levels of job satisfaction as represented in the K matrix. There was good support for the hypothesis that happy workers would be more productive than unhappy ones, as the means of the two groups differed significantly on all PRS dimensions when tested at the alpha of 0.01.

Table 8 displays the average values of the variables that influence performance. The results of this study show that there is a statistically significant relationship between each job-related element and the ensuing effects on productivity. There is a direct causal relationship between job-related characteristics and productivity. According to the results in Table 8, job-related characteristics (such as quality of work-QW and quantity of work-QuW, job knowledge-JK, cooperativeness-CO, undependability-UD, initiative-IN, creativity-CR, and personal growth-PD) positively affect performance outcomes.

As can be seen in Table 9, job satisfaction increases with age, education, and length of employment. Age, tenure, and performance on the job were all found to correlate positively, however education and performance did not. Finally, there is a vigorous relationship between

performance and satisfaction in one’s profession.

Table 10 shows that there is a statistically substantial positive correlation between job performance and job satisfaction. Except for employment position, open communication, rewards for outstanding work, and favorable relationships with coworkers, all components of the workplace were positively correlated with performance. There is a substantial positive association between job satisfaction and compensation, job satisfaction and job security, job satisfaction and workplace autonomy, job satisfaction and workplace engagement, and job satisfaction with recognition for good performance. Not only did it find a negative correlation between job happiness and employment status, but also between job satisfaction and working circumstances, and between job satisfaction and frank communication in the workplace.

Table 11 shows that at the 5 % level of significance, the variables income, promotion, job security, working conditions, recognition, and participation in decision making all have a substantial impact on employees’ performance on the job. It can be seen that the p values for the calculated t-statistics for each of the model coefficients are less than 0.05, indicating that all of the model coefficients are significant at the 5 % level of significance, with the exception of Job status, Behaviour of boss, Open communication, Autonomy in work, and Relation with colleagues. Thus, the computed multiple linear regression equation for job satisfaction includes only the most important pay facilities, working environment, training courses, encouraging factors, and motivating factors as independent variables (predictors). According to the delivered statistical gauges, as shown in Table 10, the model only includes 6 (six) job related factors of independent variable; pay, promotion, job security, working conditions, recognition, and participate in decision making. Results suggest that a total of 59.5 % of employee performance may be attributed to factors like pay, promotion, job security, working conditions, recognition for good work, and input into decision making. Six of the job characteristics listed above was determined to be causal factors. Job-related factors were found to be significant predictors of job satisfaction (beta values of 0.168, 0.189, 0.185, 0.166, 0.062 and 0.151). Certain characteristics (independent variables) associated with the work may have significantly influenced performance, as suggested by the equation.

5. Discussion

The following justifications are presented in light of the arguments for and against the hypotheses that emerged throughout the literature review and the current findings;

The results show that there are considerable disparities in job satisfaction amid the satisfied and the dissatisfied age groups, and that senior personnel (foremen) appear to be more satisfied with their jobs than younger workers. Furthermore, it demonstrates the level of satisfaction

Table 6
Levene’s Performance Evaluation Form equality of error variances test by job satisfaction.

experienced people had while on the job. Participants who reported being satisfied had much more experience than those who reported being dissatisfied, as measured by years in the workforce. Zeb et al. (2020) found that as people get older, they become satisfied in their current positions. When compared to the workforce, foremen are older and more experienced, as shown in Tables 3, 4, and 5. In a similar vein, this research discovered that foremen had significantly more experience than lower experienced workforces, and that happy employees had significantly greater experience than unhappy workforces. The mean dissatisfaction score did not differ significantly between education levels. Employees, in particular, have significantly higher levels of education than foremen. The recent research lends strong credence to Gazi et al.'s (2022) conclusion that varying degrees of job satisfaction exist among distinct groups of workers. Married workers report higher levels of satisfaction than their single counterparts, consistent with the findings of Gazi et al. (2022), who also revealed a statistically significant change in equally job satisfaction and marital status (Table 5). It proves that the SD-ratio for that age group is statistically significant. When controlling for factors like education, experience, and marital status, there is a large gap in how satisfied workers are with their jobs compared to foremen. Therefore, the result only partially rejects the alternative hypothesis (H1). The findings of this study are supported by previous research on the effects of age, education, and experience on job satisfaction (Omar et al., 2020; Yaya, 2020; Inayat et al., 2021; Satorre, 2022; Kumar, 2022). Recent research shows that there is a wide range of job satisfaction, educational attainment, years of experience, and marital status among sugar sector workers (Tables 3,4,5 and 9). When comparing our results with earlier studies, it is important to mention that certain data supports our decision to reject Hypothesis 1. For example, (Yuan et al., 2023; Gazi et al., 2023) also discovered a notable influence of individual characteristics on job satisfaction among workers in the industrial sector. Nevertheless, divergent perspectives are present, as seen by (Fikire, 2021; Arif et al., 2022), which have documented equivocal or contradictory findings. The observed heterogeneity may be ascribed to disparities in sample characteristics, measurement instruments, or cultural contexts. The current study's findings are consistent with those of Syamsudin et al. (2022), who found that workers with more education were more satisfied with their jobs. All job-related characteristics, except employment status, are significantly connected with job satisfaction, as shown in Table 11. There were no discernible variations in supervisor or coworker attitudes or actions amongst satisfied and dissatisfied respondents. Therefore, the present study's results are consistent with the second null hypothesis (H2). Nuangjamnong (2022) came to similar conclusions. It was discovered that foremen enjoy their jobs more than regular workers do. According to research by Ni et al. (2022) employees who have positive relationships with their coworkers and direct supervisor tend to be happier in their jobs (Gazi et al., 2023). The results show that there was no significant difference in worker and foreman satisfaction, as determined by the statistical value. However, foremen reported a higher level of satisfaction with their jobs than did regular employees. The rejection of Hypothesis 2 is consistent with the findings of Yuan et al. (2022) which highlight the significance of job-related factors in influencing job

satisfaction among industrial workers. Nevertheless, it is crucial to acknowledge the presence of contradictory findings, as shown by (Anis et al., 2022; Islam et al., 2020), wherein certain researchers failed to identify a statistically significant correlation. The differences seen could be ascribed to variances in industry sectors, organizational cultures, or research methodology utilized in various studies. This study's findings reveal that workers' levels of job satisfaction significantly affect their performance on the job as a behavioural component in an industrial setting. Therefore, employees' personality greatly affects work ethic and performance. Satisfaction in one's employment acts as a moderator between the various jobs factors that have an influence on performance. Occupational satisfactions have an indirect effect on performance through demographic and occupational variables. Researchers have found that happy workers are more productive and successful (Bayona et al., 2020; Tee et al., 2023; Mikhaylov, 2023). The fallouts showed a noteworthy positive correlation between individual traits and occupational success (Tables 5 and 9). Furthermore, the present study's results demonstrated a strong association between practically all characteristics of the job and job performance (Tables 8, 10 and 11). The findings of Kumar (2021) were confirmed by this study. Quality of work, knowledge, quantity of work, initiative, creativity, co-operation, undependability, and personal development were all found to be significantly impacted by factors of job satisfaction (job related factors) in the current study (Table 11). Novariani and Ramli (2020) also found a connection between increased productivity and contentment in one's employment. Findings by Mariam and Ramli (2022) show that dissatisfaction with one's employment leads to a decline in performance. Research by Yusuf (2019) shows that job satisfaction has a direct impact on work behaviour, and in particular, performance. It has also been validated that both personal traits and elements of the job can affect productivity while mitigating the unfavorable effects of job satisfaction. The results of this study show that work quality, quantity, job knowledge, initiative, creativity, cooperation, dependability, and personal growth all have a substantial impression on performance outcomes (Table 8). The results also revealed that happy workers were more likely to be creative, collaborative, and proactive in their approaches to a wide range of tasks. In light of these results, the study's null hypothesis (H3) is supported. Our findings align with prior research, indicating that our acceptance of Hypothesis 3 is in line with multiple studies that highlight the favorable association between job satisfaction and job performance among industrial workers in Bangladesh (Gazi et al., 2023; Dai and Akey-Torku, 2020; Zeb et al., 2020; Karaferis et al., 2022). This discovery corroborates the widely accepted notion that happy and contented employees are more prone to exhibiting improved job performance. Nevertheless, it is imperative to recognize opposing perspectives, as evidenced by Yoo et al. (2019), and Abdullah et al. (2023), which revealed intricacies in this correlation depending on particular contextual variables. The results of the study provided strong evidence in favour of the theory. Job satisfaction amongst workers in Bangladesh's manufacturing sector, specifically the sugar industry, has been the subject of research. This study's findings illuminated the linking between job satisfaction and performance for workers in the industrial sector. The consequences of this study are extensive. Almost everyone believes that being happy at

work affects performance (Gazi et al., 2023; Wang et al., 2023). This study's findings suggest that the connection between the two may not be causative. When job contentment is linked with organizational camaraderie as work behaviour, it may have an impact on performance.

There are a few things about this study that make it exceptional. In conclusion, research of this nature with participants from Bangladesh's sugar sector is quite rare. The completion of the study by the scholars on the given issue will be remembered as a watershed point in the history of Bangladesh. Numerous studies have examined the link between contentment in one's job and efficiency on the job. There are many studies underway and more planned, but we still know too little about how the sugar industry affects workers' productivity and happiness on the workplace. Our research is more novel and fundamental, despite the fact that the sugar industry has a smaller body of literature. A common unit of measurement was employed for the data analysis. Direct interviews were used for data collection, ensuring credible support and scores within predicted ranges for reliability and validity.

6. Conclusion

The purpose of this research is to learn how satisfied workers' attitudes and actions affect their performance as one of job behavior on the job. According to the studies, satisfied workers are more productive and contribute to the company's overall success. However, disgruntled workers have a negative impact on productivity and growth. According to the results, this is a worldwide trend, and successful businesses recognize the need of investing in their employees' productivity and happiness. It is in their best advantage to investigate methods of increasing worker satisfaction. In conclusion, our study, "Analyzing the Impact of Employee Job Satisfaction on Their Job Behavior in the Industrial Setting: An Analysis from the Perspective of Job Performance," shed light on the complex relationship between job satisfaction, personal traits, job-related parameters, and job performance among Bangladeshi industrial workers. The first hypothesis was that personal attributes do not affect respondents' job happiness. Our data invalidate this notion, demonstrating the complex link between personal qualities and job happiness. This discovery advances scientific understanding of industrial workers' job satisfaction's many components. Our second hypothesis, that job-related factors do not statistically affect respondents' job satisfaction, was likewise rejected. This emphasizes the relevance of job-related elements in understanding and improving industrial worker job satisfaction. Our third hypothesis that satisfaction with their jobs influences Bangladesh's industrial workers' performance is a major advance in understanding. Our research confirms the link between job happiness and performance and gives a deeper picture of how these variables interact in the Bangladeshi industrial setting. The careful research and empirical evidence supporting these findings give our paper scholarly significance. We improved our understanding of job happiness, personal qualities, job-related factors, and job performance by rejecting and accepting hypotheses based on our data. These findings have wider implications for industrial human resource management, helping companies improve employee satisfaction and performance. Workers in Bangladesh's manufacturing industry reported high levels of satisfaction with their jobs, with the mean satisfaction of senior personnel (foremen) being greater than that of workers. There was a large disparity between the averages of the oldest and youngest groups. Older, more experienced, and married workers report higher levels of job satisfaction than their younger, single counterparts. Policymakers in the industrial sector should create a number of programs aimed at the existing young workforce in order to increase job satisfaction. The groups of participants with both more life experience and lower levels of education reported higher levels of happiness. In order to keep and recruit skilled workers, the sugar mill's management may adopt some additional measures. The findings of this study demonstrate that job performance is directly related to employee happiness as a dimension of workplace behaviour. Both individual and organizational factors those

with bearing on productivity in one’s line of work influence the many components of job satisfaction. It has been determined that occupational considerations are the most important. Evidence between employee performance and job happiness was found in the industry sector in Bangladesh. Based on these results, it is recommended that the Bangladeshi industry priorities initiatives aimed at enhancing employee performance.

In conclusion, our research illuminates the complex links between employee job satisfaction and job performance in Bangladesh’s industrial landscape, adding to the scholarly literature. Our findings inspire further study and offer practical advice for improving employee satisfaction and performance in comparable circumstances.

6.1. Theoretical contribution

The research, titled "Analyzing the Impact of Employee Job Satisfaction on Their Job Behavior in the Industrial Setting: An Analysis from the Perspective of Job Performance," makes a valuable contribution to the theoretical field by providing a detailed understanding of how employee job satisfaction affects their job behavior in an industrial environment. The study offers a holistic perspective by combining models of job happiness and job performance, thus filling gaps in the current literature. The research extends beyond conventional evaluations, examining multiple facets of job conduct and acknowledging the distinct dynamics of the industrial environment. This approach provides useful insights into the influence of satisfaction on several elements of employee behavior, so contributing to a comprehensive theoretical framework for both scholars and practitioners.

6.2. Managerial implications

The results of this study have significant managerial significance for firms that operate in industrial environments. By acknowledging the direct correlation between job satisfaction and job conduct, firms may proactively oversee and augment employee satisfaction, thus enhancing job performance. This entails allocating resources towards employee engagement activities, customizing training programs to address specific workplace behaviors driven by satisfaction, aligning performance appraisal and recognition systems, and adopting well-being initiatives to foster a happy work environment. By integrating these observations into managerial strategies, businesses can cultivate a work environment that promotes employee contentment and favorable job conduct, resulting in improved overall organizational achievement.

6.3. Limitations of the study and future research directions

Like any other research, this one has certain caveats of its own. The 5 industry was chosen as our sample of publicly-owned sectors; other sectors were not included. So it’s probable the researcher can’t infer the outcomes to the whole sector across the country. Therefore, only 300 out

of millions of workers participated in the study, which concentrations on how job pleasure affects job behavior, in particular on the performance of industrial workers. The research’s population size is also a limitation. Researchers were hampered in their efforts to provide high-quality findings due to insufficient sample sizes necessitated by a lack of resources, financial support, and time. With regards to the limitations of the current study, the relatively large sample size, and the overall industry, it is hoped that future researchers will be able to generate reliable results using cutting-edge research approaches. The probability of approximation bias in some process is yet another limitation. In our research, we relied on two well-known measures, although also used some older methods of analysis. In subsequent studies employing the improved methodology, a larger sample will be able to construct an emerging research framework. In such a case, it may be necessary to take into consideration a wider range of socioeconomic and vocational aspects. Bangladeshi whole industrial sector should be included in the study if researchers want to get a complete picture of how employee satisfaction at work affects their actions across the country. The introduction of more comprehensive measurement scales and questionnaires, as well as more recent iterations of data analysis software, could greatly improve the reliability of future studies. It is important for future researchers to dig more into the link between job behaviour (performance) and contentment in the workplace.

The findings of this study are not limited within the five state owned industries in Bangladesh. Many workers in Bangladesh consider other sectors to be analogous to the others. The study’s findings can be used to improve working conditions for employees and boost productivity, and similar barriers can be removed in other sectors. The findings of this study are expected to be useful for the betterment of employees in the Bangladesh industry sector to the industrial leaders, board of directors, factory authorities, and trade union leaders. Workers’ advocacy groups such as the Industrial Sector Governing Council of Advisors, Ministry of Industry, and Department of Labor, among others will use the study’s findings to better understand and satisfy the demands of their constituents, leading to higher levels of job satisfaction and performance.

Above all, from the gaps identified, several promising avenues for future research are outlined. For one, scholars could develop and test targeted interventions designed to boost job satisfaction in different sectors to learn exactly what works to boost employee productivity. Second, an analysis of how interventions aimed at diversity, inclusion and equity impact job satisfaction and behavioral outcomes of employees can offer practical recommendations, particularly in the case of Bangladesh, which is increasingly diverse in its workforce. What’s more, research in the future could create or use broader measures that include subjective as well as objective measures of job satisfaction, to provide a more holistic snapshot of the employee experience. Studying the effects of environmentally conscious work on job satisfaction and productivity might also pay off as corporate social responsibility becomes an increasingly central concern in the industrial world. Finally, comparative analysis between regions or countries could build a better picture of

how external economic and political forces influence job satisfaction and performance in various industrial settings.

Ethics approval and consent to participate

This study approval constituted ethical clearance by the School of Management Human Research Ethics Committee of School of Management, Juijiang University, China. Informed consent was obtained from all participants to the collection, storage, and use of their given information for research purposes. All the procedures were followed in accordance with the relevant guidelines and regulations.

Funding

This research project was supported by the Rabdan Academy, United Arab Emirate and partially supported by INTI International University, Malaysia.

Ethical statement

In compliance with local law and institutional regulations, an ethical assessment and permission were not necessary and obtained from ethics committee for this study involving human subjects. Similarly, written informed consent was not required from participants in accordance with national laws and institutional standards. There was no coercion used to obtain responses, and all participation was voluntary. Prior to posting or sharing the questionnaire on social media, participants were informed about the study’s purpose and how it could benefit them. It was made clear that participants would not receive any monetary compensation for their participation. An open forum was provided for participants to ask questions and gain insight into the study, and they were informed that they could drop out at any time.
